

Team 6: Browser Extension for Tracking Pixels (monoPix-scout)

Mario Belmonte (mbelmont), Adrian Muñoz (adrianmu)

Personal Contributions

- Managed and maintained orderly structure throughout the GitHub repo file management system
- Created, edited README file to best summarize the project
- Worked on every script/file present on the repository
- Developed “scoring system” for danger levels
- Made major changes in UX
- Demo-site creation
- Worked on previous Monkey Patch hooking method for beacon and fetch calls
- Tracking pixel blocking and replacement with matching canvas size

LLM Contributions

- Aided in initial breakdown of general browser extension files, their job, and how it relates to our project
- Generated varying size logo needed for Google Chrome integration
- Suggested and helped in understanding how to write the current Monkey Patch “Injection” method for hooking the beacon and fetch calls
- Helped in the editing process of the README file

Lessons Learned

- After working rigorously, I can safely say that I’ve gained a lot of experience in working with JavaScript as well as HTML. In my future endeavors I won’t feel as intimidated by new projects for simple reasons like a fear of learning to work with a new coding language.
- The whole aspect of file management being a requirement for building a browser extension was new to me. I had no idea there was such a division of labor between scripts for UX and functionality.
- By making the demo-site I realized how simple it is to make a sample, alpha build of a website even if all it consists of is images and text.
- Previous to this project I had no understanding of concepts like tracking pixels, beacons, and fetch calls. The concepts upon which they relied on had been covered in class, but it was a bit difficult to understand how it all tied together to form these exploitation techniques.
- I was most curious about the entire idea of the Monkey Patch hooking method to ping when obvious beacon and fetch calls were made. At the time it seemed like such an ingenious idea, but looking back on it now it seems to hinge entirely on the fact that these API-based function calls are easily detectable by the environment.
